Dimension Reduction

- One-hot encoding with TFIDF can produce very long vectors: Imagine a vocabulary one million words per language with 100 languages.
- A solution is to produce dense vectors using a dimension reduction.
- Such vectors are also called **word embeddings**
- The reduction is similar to a principal component analysis (PCA) or a singular value decomposition (SVD)
- The embedding of a word can be constant (static) or depend on the context (contextual)

Creating word embeddings

- ① We can derive word embeddings from corpora. Their construction is then similar to that of language models;
- ② We can also introduce an embedding layer as input to a neural network. The embedding parameters are then trainable.
- ③ We can finally pretrain embeddings with a corpus and fine-tune them on an application.

A Data Set: *Salammbô*

A corpus is a collection – a body – of texts.

Each character is modeled by a vector of chapters.

Singular Value Decomposition

There are as many as 40 characters: the 26 unaccented letters from *a* to *z* and the 14 French accented letters: *à, â, é, è, ê, ë*, etc.

Singular value decomposition (SVD) reduces these dimensions, while keeping the resulting vectors semantically close

X is the $m \times n$ matrix of the letter counts per chapter, in our case, $m = 30$ and $n = 40$.

We can rewrite X as:

$$X = U\Sigma V^T,$$

where

- U is a matrix of dimensions $m \times m$,
- Σ , a diagonal matrix of dimensions $m \times n$, and
- V , a matrix of dimensions $n \times n$

The diagonal terms of Σ are called the **singular values** and are traditionally arranged by decreasing value.

To reduce the dimensions, we keep the highest values and set the rest to zero.

Code Example

Jupyter Notebook `ch09_PCA.ipynb` on the GitHub course repository

Vector Space Model

With the vector space model, we represent:

- Documents in a space of words (the words they contain) or
- Words in a space of documents (the documents that contain them).

Here, the rows are the words in the corpus, and the columns, the documents.

| Words\ D# | D_1 | D_2 | D_3 | ... | D_n |
|-----------|---------------|---------------|---------------|-----|---------------|
| w_1 | $C(w_1, D_1)$ | $C(w_1, D_2)$ | $C(w_1, D_3)$ | ... | $C(w_1, D_n)$ |
| w_2 | $C(w_2, D_1)$ | $C(w_2, D_2)$ | $C(w_2, D_3)$ | ... | $C(w_2, D_n)$ |
| w_3 | $C(w_3, D_1)$ | $C(w_3, D_2)$ | $C(w_3, D_3)$ | ... | $C(w_3, D_n)$ |
| ... | ... | ... | ... | ... | ... |
| w_m | $C(w_m, D_1)$ | $C(w_m, D_2)$ | $C(w_m, D_3)$ | ... | $C(w_m, D_n)$ |

$C(w_i, D_j)$ can be Boolean values, counts, $tf \times idf$, or a metric similar to $tf \times idf$ as in **latent semantic indexing**.

We can extend singular value decomposition from characters to words.

Word Embeddings

A PCA applied to this matrix will result in dense vectors representing the words.

Transposing the matrix, we represent documents with dense vectors
We compute the word embeddings with a singular value decomposition, where we truncate the matrix $\mathbf{U}\Sigma$ to 50, 100, 300, or 500 dimensions.
The word embeddings are the rows of this matrix.

Word Similarity

Contrary to one-hot encoder words, we can measure the similarity of two dense vectors \mathbf{u} and \mathbf{v} .

We usually measure the similarity between two embeddings \mathbf{u} and \mathbf{v} with the cosine similarity:

$$\cos(\mathbf{u}, \mathbf{v}) = \frac{\mathbf{u} \cdot \mathbf{v}}{\|\mathbf{u}\| \|\mathbf{v}\|},$$

ranging from -1 (most dissimilar) to 1 (most similar) or with the cosine distance ranging from 0 (closest) to 2 (most distant):

$$1 - \cos(\mathbf{u}, \mathbf{v}) = 1 - \frac{\mathbf{u} \cdot \mathbf{v}}{\|\mathbf{u}\| \|\mathbf{v}\|}.$$

Embedding Layer in PyTorch

PyTorch has an embedding layer. This is just a lookup table.
From PyTorch documentation:

```
embedding = nn.Embedding(10, 3)
input = torch.LongTensor([[1, 2, 4, 5], [4, 3, 2, 9]])
embedding(input)
```

```
embedding = nn.Embedding(10, 3, padding_idx=0)
input = torch.LongTensor([[0, 2, 0, 5]])
embedding(input)
```

Loading pretrained embeddings:

```
embeddings = nn.Embedding.from_pretrained(
    torch.FloatTensor(embedding_matrix),
    freeze=False,
    padding_idx=0)
```

Word2vec Embeddings

word2vec is another kind of embeddings that comes in two forms: CBOW and skipgrams.

CBOW uses a neural network architecture to predict a word given its surrounding context

The set up is similar to fill-the-missing-word questionnaires.

The missing word is called the focus word

CBOW embeddings corresponds to neural network parameters

The embeddings are trained on a corpus

Word2vec Example

Using contexts of five words and training sentences such as:

Sing, O goddess, the anger of Achilles son of Peleus,

we generate a training set of contexts deprived of their focus word (X) and the focus word to predict (y):

$$X = \begin{bmatrix} \text{sing} & \text{o} & \text{the} & \text{anger} \\ \text{o} & \text{goddess} & \text{anger} & \text{of} \\ \text{goddess} & \text{the} & \text{of} & \text{achilles} \\ \text{the} & \text{anger} & \text{achilles} & \text{son} \\ \text{anger} & \text{of} & \text{son} & \text{of} \\ \text{of} & \text{achilles} & \text{of} & \text{peleus} \end{bmatrix}; y = \begin{bmatrix} \text{goddess} \\ \text{the} \\ \text{anger} \\ \text{of} \\ \text{achilles} \\ \text{son} \end{bmatrix}$$

CBOW Architecture

We train a neural network to get the CBOW embeddings: N dimension of the embeddings, V size of the vocabulary. First matrix (V, N) , second (N, V) .

Examples

Words closest to *he*, *she*, *London*, *table*, and *Monday* with CBOW embeddings trained on a corpus of Dickens novels:

he ['she', 'they', 'it', 'be', 'that']

she ['he', 'they', 'it', 'i', 'be']

london ['paris', 'england', 'town', 'india', 'dover']

table ['desk', 'counter', 'box', 'sofa', 'ground']

monday ['sunday', 'thursday', 'saturday', 'noon', 'wednesday']

Glove Embeddings

There are many kinds of word embeddings: Global vectors (GloVe) is one of them

We can replace documents by a context of a few words to the left and to the right of the focus word: w_i .

A context C_j is then defined by a window of $2K$ words centered on the word:

Word: w_i ,

Context: $w_{i-K}, w_{i-K+1}, \dots, w_{i-1}, w_{i+1}, \dots, w_{i+K-1}, w_{i+K}$,

where the context representation uses a bag of words.

We can even reduce the context to a single word to the left or to the right of w_i and use bigrams.

Glove Embeddings

We store counts of word pairs (w_i, w_j) in a matrix:

| Words | w_1 | w_2 | w_3 | ... | w_n |
|-------|----------|----------|----------|-----|----------|
| w_1 | X_{11} | X_{12} | X_{13} | ... | X_{1n} |
| w_2 | X_{21} | X_{22} | X_{23} | ... | X_{2n} |
| w_3 | X_{31} | X_{32} | X_{33} | ... | X_{3n} |
| ... | ... | ... | ... | ... | ... |
| w_n | X_{n1} | X_{n2} | X_{n3} | ... | X_{nn} |

X_{ij} is the number of times word w_j occurs in the context of word w_i , for instance 10 words to the left and 10 to the right

To train the embeddings, we minimize the loss (simplified):

$$J = \sum_{i,j=1}^V (\mathbf{w}_i \cdot \mathbf{w}_j - \log X_{ij})^2,$$

where \mathbf{w}_j , resp. \mathbf{w}_i , is the embedding vector of word of index j , resp. i .

Using Word Embeddings

We can use word embeddings to replace one-hot vectors as they will make the representation much more compact.

In a text categorization task, for instance, you would use a window of words (for instance the 200 first words of the document), where each word would be represented by its embedding.

The input layer is then called an **embedding layer**.

The embeddings are trainable parameters that you can initialize with pre-trained embeddings or random values.

Popular Word Embeddings

Embeddings from large corpora are obtained with iterative techniques
Some popular embedding algorithms with open source programs:

word2vec: <https://github.com/tmikolov/word2vec>

GloVe: Global Vectors for Word Representation

<https://nlp.stanford.edu/projects/glove/>

fastText: <https://fasttext.cc/>

To derive word embeddings, you will have to apply these programs on a very large corpus

Embeddings for many languages are also publicly available. You just download them

gensim is a Python library to create word embeddings from a corpus.

<https://radimrehurek.com/gensim/index.html>
